**Project Background:** BSEE is charged with the responsibility to permit, oversee, and enforce the laws and regulations associated with the development of energy (oil and natural gas) resources on the Outer Continental Shelf (OCS). BSEE's Oil Spill Preparedness Division (OSPD) is responsible for developing and administering regulations (30 CFR 254) that oversee the oil and gas industry's preparedness to contain, recover, and remove oil discharges from facilities operating seaward of the coastline. Current regulations require that operators of these offshore oil and gas facilities submit an Oil Spill Response Plan (OSRP) that identifies the procedures and contracted spill response resources necessary to respond, to the maximum extent practicable, to a facility's worst case discharge (WCD).

It has been nearly two decades since BSEE's OSRP regulations have been updated. During this time, changes occurred in drilling trends as well as the risks associated with oil spills. The national response system within the United States has also matured over time; Regional Contingency Plans (RCPs) and Area Contingency Plans (ACPs) have been approved that contain extensive oil removal and protection strategies, including the preauthorized use of dispersants and in-situ burning. New technologies, such as remote sensing, are now commercially available and stand poised to transform our abilities to respond offshore.

In an effort to understand this changing environment, BSEE awarded a contract to Booz Allen Hamilton (BAH) in 2014 to catalogue the changes in the WCD scenarios found in OSRPs for the OCS, and evaluate the oil spill response industry's capabilities to mitigate these spills through existing equipment stockpiles and technology using the strategies outlined in today's RCPs and ACPs. BAH completed the study, which is contained in *Volume I: Worst Case Discharge Analysis* and *Volume II: Oil Spill Response Equipment Capabilities Analysis*, in February 2016.

**Peer Review Description:** As parts of this two volume study may be used in the future to support an anticipated rulemaking effort, and may also meet the criteria for "influential scientific information" under the Office of Management and Budget's Memorandum on Peer Review (OMB M-05-03), BSEE determined that selected sections of the study should be subjected to a peer review. EnDyna was contracted in June 2016 to provide coordination and oversight of the peer review. EnDyna selected three scientific experts who prepared written comments and then participated in a 2-day peer review panel held on September 8-9, 2016. EnDyna summarized and synthesized the reviewer comments into a final summary report, which was completed in January 2017.

BSEE defined the scope of this peer review through the use of a prepared set of Charge Questions. The peer reviewers were directed to keep their written comments focused on the modeling and final recommendations contained within the study. The review was technical in nature, and did not extend to the regulatory benchmarking analysis, Deepwater Horizon spill response case study, the analysis of changing regional WCD profiles, or other sections of

Volumes I and II that were not related to the modeling or the recommendations. The peer reviewers could refer to these out-of-scope sections when providing written comments on the recommendations section. The following table contains the charge questions addressed by the peer reviewers:

Volume I–Worst Case Discharge Analysis		
1.1	Were the Worst Case Discharge (WCD) sites selected for analysis a valid sample to evaluate the probabilities and scope of oil contacting the environment in each region?	
1.2	Are the limitations and uncertainties clearly identified and adequately characterized for the oil plume, fate and effects, and transport mechanisms used in the stochastic trajectory modeling?	
1.3	Are the assumptions of the modeling clearly defined and appropriate?	
1.4	Are there strengths or weaknesses of the analytical methods used for the modeling?	
1.5	Do the modeling results describe with reasonable accuracy the probability, scope and minimum travel times for oil to potentially contact the environment in the event of a WCD for the selected scenarios?	

#### Volume II–Oil Spill Response Equipment Capabilities Analysis

2.1	Are the limitations and uncertainties clearly identified and adequately characterized for the deterministic trajectory and response countermeasure modeling?
2.2	Are the assumptions of the modeling in Volume II clearly defined and appropriate? Assumptions evaluated should include, but are not limited to: a) Fate and transport of the oil b) Application of temporary source control measures c) Application of spill response countermeasures.
2.3	Are there strengths or weaknesses of the analytical methods used for the modeling?
2.4	Are the conclusions drawn from the oil spill response capabilities analysis logical and appropriate based on the modeling results?
2.5	Are the recommendations logical, appropriate, and supported by the analysis and modeling results? The scope of the recommendations pertains to all recommendations, not just those derived from the modeling results.

**Peer Review Comments and BSEE's Response:** The reviewers provided a range of comments on the study report, ranging from general agreement regarding the methodology and assumptions used, to concerns about the modeling complexity and various uncertainties associated with the modeling results. The reviewers provided their impressions on the choice of models that were used; the modeling in Volume I, including concerns regarding uncertainties, the sampling of the ensemble state or "situation space", and the generation of droplet size distributions (DSDs); the modeling in Volume II; and recommendations.

In general, the reviewers felt the models used were well-developed, tested, and widely accepted; however, they also stated using complex models over extended periods of time without a means of data assimilation results in data with compounding levels of uncertainty. The reviewers also cautioned that limiting the number of simulations and using fixed parameters for some of the scenario parameters results in data sets that may not necessarily describe the full variability of all the possible outcomes, which may also create uncertainties associated with the modeling results. Despite these observations regarding uncertainty and ensemble situation space, the reviewers generally agreed that the modeling results were adequate to support the objectives of the study and effectively informed the study's recommendations.

BSEE acknowledges the concerns regarding modeling complexities, sampling limitations, and resulting uncertainties, but believes the modeling outcomes represent the highest quality of data that can be generated under the circumstances. Given the general agreement of the reviewers that the modeling results were sufficient to meet the objectives of the study, BSEE does not believe it is necessary to conduct additional or revised modeling. BSEE also does not believe it is necessary for the research team to make additional changes to the study recommendations based on the overall feedback provided in the peer review report. BSEE will, however, give full consideration to all of the reviewer's comments, especially those concerning the nature of the modeling results with respect to uncertainty, etc, when evaluating the report's findings for the purposes of informing the agency's efforts to update the oil spill response plan regulations.

In many cases, the reviewers did suggest including more information in the study report on the internal processes and algorithms used within the models. This information was purposely not included in the report, mainly due to concerns over the very large size and complexity of the document. Given this constraint, and the fact that these two models are well tested and widely accepted, it was agreed by both BAH and BSEE that is was not essential to list out in detail the internal mechanics of the two models that were used. The study does provide a significant amount of detailed information on the assumptions that were made and the methods that were used in order to effectively model the application of the various response countermeasures. Reference documents containing detailed descriptions of the basic modeling mechanics were provided to the peer reviewers once it was made known that they needed access to this information in order to facilitate their review. While the information provided answered the reviewer's questions, and generally met their needs to finish the review, the reviewers still felt

inclined to recommend that this detailed information be included in the study reports. BSEE, however, does not believe that this level of modeling detail needs to be present in the report, and does not intend to award a new contract to BAH for the purposes of including this information in the study report. BSEE can provide further references, separate from the report, to any parties that are interested in reviewing the internal mechanics of the models used.

A much more detailed listing and description for each of the subject areas addressed in the reviewers' comments, as well as BSEE's responses to these comments, are contained in the accompanying appendix, "Peer Review Comment & Agency Response Matrix".

BSEE would like to acknowledge and thank the peer review team; their efforts have better informed the agency on the inherent strengths and weaknesses of the processes used and the resulting information that was generated in the study report.

#### *Oil Spill Response Plan Equipment Capability Review*

## # Page Peer Review Comment

Agency Response

General Impressions				
Choic	Choice of Models Used			
A1	11	Two reviewers commented that the study used industry standard models that have been well tested and are widely applied over many years.	BSEE agrees that OILMAPDeep and SIMAP are industry standard simulation packages that have undergone many years of application, testing, and refinement.	
A2	11	One reviewer commented that the models used in the study were presumed correct or acceptable when they were used as part of a formal NRDA Type A process. This reviewer also noted that multiple technical reviews of these models exist because they have been used by the ongoing DWH damage assessment process and as the NRDA Type A model.	Noted. BSEE agrees that the models are widely accepted and used for various industry and government activities.	
A3	12	One reviewer commented that many of the study's conclusions attributed to "the model" were actually little more than what an experienced spill responder would consider as common knowledge. Given that the models provided results that would be expected by an experienced spill responder, this reviewer noted that the selected models probably did not provide any obvious erroneous results.	Noted.	
A4	11	One reviewer commented that the models used to develop the study's conclusions were essentially built around a set of quite complex models and algorithms. SIMAP was encumbered with many unused parametric algorithms that may have introduced more complexity to this study than was necessary. The reviewer expressed concerns that it was not obvious that the complexity of the model components was justified. The reviewer noted that any number of simple particle tracking models would work as well as SIMAP.	The study, especially in the case of SIMAP, did use all of the model's capabilities. BSEE believes that the models chosen by the research team were well suited for conducting the study tasks; however, BSEE acknowledges the reviewers concerns that model complexities have the potential to create greater uncertainties in the modeling results.

		laboratory data. This reviewer	study.
		emphasized that it was important to	
		point out that no data are available for	
		DSDs in the parameter space of a full-	
		scale blowout, and no measurements	
		were made of DSD near the DWH	
		breakun region Given the lack of data	
		the reviewer stated that it would be	
		necessary to trust that extranolation	
		from the currently available laboratory	
		data to the field scale is appropriate. The	
		reviewer argued that this uppertainty	
		reviewer argued that this uncertainty	
		deen water blowout, the initial DCD	
		deep water blowout, the initial DSD	
		would control the late processes of oil in	
		the water column; the location,	
		thickness, and properties of oil on the	
		surface; and is an integral part in	
		evaluation of the efficacy of SSDI. The	
		reviewer emphasized that the validity of	
		such extrapolation can only be verified by	
		larger-scale experiments. The reviewer	
		also suggested that the study report	
		could perhaps recommend to BSEE the	
		need to fill this current gap with initial	
		DSD data from larger-scale experiments.	
D2	13	A reviewer commented that the effect of	BSEE agrees.
		the DSD prediction equation on the	
		modeling was most significant for	
		evaluating the efficacy of subsurface	
		dispersant injection (SSDI), because SSDI	

#	Page	Peer Review Comment	Agency Response
		was modeled in the simulations by	
		adjusting the interfacial tension (IFT)	
		between the oil and water and predicting	
		a new DSD with this IFT. The reviewer	
		stated that this approach was the current	
		practice for predicting the effects of SSDI.	
		The reviewer emphasized that if the DSD	
		prediction equation over- or under-	
		predicted the treated DSD, then the	
		modeling conclusions would over- or	
		under-predict the efficacy of SSDI. The	
		reviewer commented that the review of	
		the DWH accident supported the	
		conclusion that SSDI is an effective and	
		important response strategy for	
		accidental blowouts, and this conclusion	
		was also supported by the model results.

<i>Charge Question 1.1:</i> Were the Worst Case Discharge (WCD) sites selected for analysis a valid sample to evaluate the probabilities and scope of oil contacting the environment in each region?				
	I J J J J J J J J J J J J J J J J J J J			
WCD	Scenario	Sample Set		
F1	15	The reviewers generally agreed that the WCD sites selected for analysis were a valid sample. One reviewer stated that the study made reasonable efforts to select WCD sites that cover a wide range of potential blowout scenarios and environmental impacts, and that the study report provided a justification for selecting each WCD. Another reviewer stated that the scenarios selected adequately represented near-shore, offshore, and open-ocean WCDs in each region and made sense.	Noted. BSEE agrees.	
F2	16,19- 20	<ul> <li>One reviewer commented that the study could have selected WCD sites that addressed smaller scale features that have proven to be important in historical spills. The reviewer emphasized that each of the regions had smaller scale circulation features in their areas and the study report did not provide sufficient information about how the analysis addressed these important smaller scale features.</li> <li>Central Gulf: Details of the Mississippi Delta freshwater outflow and mixing close to the delta are intricate.</li> <li>Western Gulf: A near-shore low salinity frontal interface caused by fresh water runoff typically extends from the Atchafalalya, past Calacsieu to Galveston, which results in a convergence band that traps floating pollutants and may locally offset trajectories tens of miles to the west.</li> <li>Santa Barbara Channel: The complex eddy structure in the</li> </ul>	The SIMAP model in most cases does incorporate the smaller scale circulation features that were identified by the reviewer. In the Gulf of Mexico, the Princeton Ocean Model (POM) was used. The POM simulation did include freshwater inputs (daily discharge from 34 rivers in the northern Gulf of Mexico). Data sources used for calibration ("assimilation) include satellite sea-surface height anomaly (SSHA), sea-surface temperature (SST), moored temperatures and currents, hydrography, and drifters. The Santa Barbara Channel modeling used the Navy NRL HYCOM model. In Chukchi and Beaufort regions, the TOPAZ model, with HYCOM hydrodynamics was used. Again, the described behavior and directional shifts resulting from these smaller scale features would be captured in the hydrodynamic data sets used by the model at various times. Thus, the needed forcing data to capture the small scale features were used, but specific hindcasting attempts might not show the exact timing of these features. The modeling in the study was not intended to be used to hindcast conditions for any particular past time	

#	Page	Peer Review Comment	Agency Response
		<ul> <li>Santa Barbara Channel itself and the directional shifts associated with California Current versus Davidson Current periods around the channel are an issue.</li> <li>Chukchi and Beaufort regions, Arctic: Details of the ice cover circulation and banded currents found along the North Slope will certainly degrade the veracity of forecasts</li> </ul>	period or to accurately forecast future currents. The veracity of <i>forecasts or</i> <i>hindcasts</i> is therefore not an issue.
F3	16	A reviewer pointed out that the study was limited by the fact that only a fraction of existing wells have data within the OSRP dataset. The reviewer acknowledged that this dataset will limit the available range of sites that could be selected for the study. The reviewer stated that this limited dataset especially impacted the Gulf of Mexico Eastern Planning Area (where the selected WCD site was actually in the Central Planning Area) and the Gulf of Mexico Western Planning Area (where the sites in the OSRP dataset were well to the east of many existing wells within the planning area). <sup>SS</sup>	BSEE recommended scenarios to the research team based on the population of WCD sites that are listed in the OSRPs, fully understanding that each OSRP also covers other wells with lesser flowrate volumes. Because BSEE wanted to examine modeling scenarios that would challenge the existing response infrastructure within each region, BSEE focused primarily on the distribution of wells listed as WCDs across each area. BSEE and the research team believe the scenarios that were developed based on the OSRP WCD data is a valid representative sample of all the wells covered under the plans for the intended purposes of the study.
F4	16	A reviewer commented that in several regions, the spill sizes selected for analysis were smaller than the largest WCDs among all of the OSRP data points. The study would become more solid if the report explained why higher flow rate cases were not selected when they were present in the OSRP dataset.	Noted. Flowrate was not the only variable that drove the selection of various modeling scenario sites. BSEE and the research team worked together to select scenarios that covered a range of scenario site variables, including distance from shore, water depth, geographical locations, and oil types, in addition to flowrates. In nearly all cases, the report did provide a rationale for the selection of most sites. It did not provide a full description of why other sites were not chosen. In the case of the Southern CA planning area of the Pacific OCS Region, the 12,000 BPD WCD shown in the study scatter plots was an error, the 5,200 BPD WCD is more representative of the greatest WCDs in

#	Page	Peer Review Comment	Agency Response
			the area. In the Arctic planning area of the
			Alaska OCS region, the site listed as 85,000
			BPD has actually since been revised to
			92,000 BPD and has yet to be drilled and
			numbers verified: however, this site was not
			chosen for WCD modeling primarily because

<i>Char</i> (See	<i>Charge Question 1.3: Are the assumptions of the modeling clearly defined and appropriate?</i> (See below as well as Comment C6)			
Mode	eling Prod	cesses		
G1	21	A reviewer expressed concerns about whether the internal assumptions operating within the models were adequately described; the reviewer did state that the assumptions of the OILMAPDeep model were adequately described, with the exception of whether the model accounted for ambient currents.	OILMAPDeep is run with ambient stratification and currents from a select point. For a full description of the fate processes modeled for SIMAP simulations refer to French McCay, D.P. (2004), "Oil spill impact modeling: Development and validation. Environmental Toxicology and Chemistry" 23 (10): 2441-2456.	
G2	22	clear in the study report whether dissolution was considered as a fate process for the SIMAP simulations.	bissolution was considered in SIMAP and in the weathering and fates results (e.g., mass balance), but was not specifically presented in the report. For a full description of the fate processes modeled for SIMAP simulations refer to French McCay (2004). See reference cite above (comment G1).	
G3	20	A reviewer stated that the modeling assumptions were generally clear and well stated, with the notable exception of how the Eulerian field data were calculated from the aggregated Lagrangian particles. The study report also presented the thickness of the floating or beached oil, which was Eulerian field data and was dimensional (mass/area). The reviewer stated this should be calculated from the aggregated Lagrangian particles and possibly corrected for individual "spillet" spreading. The reviewer commented that the mathematics of these calculations were tricky and noted that the study report did not explain how the model operated for those calculations.	The model calculates mass loading (e.g., g/m <sup>2</sup> ) as opposed to a real thickness. The spillets (or Lagrangian particles), each representing some known volume of oil are overlaid on a fixed grid (e.g., the habitat grid) and the mass of the spillet is projected into the fixed grid cell. Then, the mass of all spillets are then summed within one fixed grid cell. The mass of MAHs and PAHs in the water column is contoured on a three-dimensional Lagrangian grid system. This grid (of up to 200 X 200 cells in the horizontal and up to 100 vertical layers) is scaled each time step to just cover the volume occupied by aromatic particles, including the dispersion around each particle center. This maximizes the resolution of the contour map at each time step and reduces error caused by averaging mass over large cell volumes. Distribution of mass around the particle center is described as Gaussian in three dimensions, with one standard deviation equal to twice the diffusive distance (2 <i>Dgxt</i> in the horizontal, 2 <i>Dgzt</i> in the vertical, where

			provide a good indicator of the oil removal
			contributions gained from the application of
			different response countermeasures. It

#	Page	Peer Review Comment	Agency Response
			should be noted that surface oiling and volume of oil stranded onshore were also used as indicators in addition to the length of shoreline oiled.
14	33	One reviewer emphasized that the documentation in the study report regarding the details of how oil thickness values were calculated was questionable, and suggested that a more complete explanation was needed to fully evaluate the conclusions that are based on the modeling results. This reviewer commented that it would be interesting to provide a mass balance of the thick to thin portions of the developing plume in the modeling scenarios. This reviewer could not find any information about how the model calculated oil thickness and argued that the incomplete explanation of the details of oil thickness values in the study report raised questions about this component of the response countermeasures modeling.	It is important to note that the model calculates mass loading (e.g., g/m <sup>2</sup> ) as opposed to a real thickness. The spillets (or Lagrangian particles), each representing some known volume of oil are overlaid on a fixed grid (e.g., the habitat grid) and the mass of the spillet is projected into the fixed grid cell. Then, the mass of all spillets are then summed within one fixed grid cell. It was beyond the scope and outside of the purpose for the final report to lay out in great detail the methodologies and algorithms used by the SIMAP model to calculate oil thickness, fate, and transport. This information was later provided to the review panel, which satisfied their questions and concerns regarding the study processes involved. The reviewers however elected to not change their comments due to the fact that the information necessary to answer their questions was not contained in the final report.

#	Page	Peer Review Comment	Agency Response	
<b>Char</b> appr	<i>Charge Question 2.2:</i> Are the assumptions of the modeling in Volume II clearly defined and appropriate? Assumptions evaluated should include, but are not limited to:			
а	) Fate a	nd transport of the oil		
b	) Applic	ation of temporary source control measu	res	
Oil Fa	<i>) Applice</i> ate and T	ransport Modeling		
J1	28	One reviewer expressed concerns that the documentation in the study report did not explain what combination of algorithms was used in the analysis related to assumptions about oil fate and transport. The reviewer suggested including additional documentation in the study report to explain how oil fate and transport assumptions were defined.	<ul> <li>Providing a detailed description in the final report of how each fate and transport process is incorporated into the SIMAP model is not necessary information to support the objectives of the study. Information on these assumptions and processes can be reviewed in French McCay (2004) and French McCay (2016), for a description of the algorithms used in SIMAP for oil weathering.</li> <li>French McCay, D.P. (2004), "Oil spill impact modeling: Development and validation. Environmental Toxicology and Chemistry" 23 (10): 2441-2456.</li> <li>French McCay, D.P., Zhenghai. Li, Mathew Horn, Deborah Crowley, Malcolm Spaulding, Daniel Mendelsohn, and Cathleen Turner (2016), "Modeling Oil Fate and Subsurface Exposure Concentrations form the Deepwater Horizon Oil Spill".</li> </ul>	
			Please also refer to French McCay et al. (2015), which is RPS ASA's oil fate modeling technical report for DWH, which is available for download at: <u>https://www.fws.gov/doiddata/dwh-ar- documents/830/DWH-AR0285776.pdf</u> .	
J2	28	One reviewer suggested that the study report should clearly itemize all fate processes modeled for the SIMAP simulations, especially whether dissolution was considered as a fate process for the SIMAP simulations.	BSEE disagrees. Providing a detailed description of how each fate process is incorporated into the SIMAP model is not necessary information required to support the objectives of the study final report. Instead, this information was provided to the peer review panel members for their assessment of the project.	

#	Page	Peer Review Comment	Agency Response
J3	28	Another reviewer commented more	Noted.
		generally that the assumptions in the	
		report were documented by experienced	
		experts and met the study's objectives.	
		More specifically, for oil fate and	
		transport, this reviewer stated that the	
		model simulations provided reasonable	
		oil thickness and viscosity thresholds	
		used to determine suitability for	
		mechanical, in-situ burning, or dispersant	
		applications. This reviewer referenced	
		page 8 of the report.	
Temp	orary So	urce Control Measures	
K1	29	One reviewer stated that the timelines	BSEE agrees.
		for application of temporary source	
		control measures appeared to be a	
		reasonable compromise between the	
		times required during DWH (which were	
		longer due to the fact that this

		accessibility of skimming vessels to appropriate surface oil, travel time for skimmers between slicks and staging sites, the limited spatial extent of the coverage provided by the skimming vessels, and the difficulties of finding and tracking recoverable oil. This reviewer commented that these details were not specified in the study report and argued that providing those details would make it easier to evaluate the model simulations for mechanical removal.	of the application of the oil removal rates factored in initial response times that involved transits from staging bases to the removal areas. For mechanical recovery, the modeling assumed these assets would conduct offloading operations onsite to other secondary storage resources, and therefore did not factor in additional transits back and forth between the removal areas and staging sites. Removal rates for surface dispersants did factor in transit times back and forth between staging airports and the spill site. The study also makes an assumption that aerial surveillance and tracking is being effectively used to keep all removal assets actively working in thick oil. Oil encounter rates and the spatial coverage for each removal system were factored into the development of each system's oil removal rates through the use of the ERSP, EBSP and EDSP Calculators.
L3	30	A reviewer commented generally that the assumptions in the report were documented by experienced experts and met the study's objectives.	Noted.

*Charge Question 2.3:* Are there strengths or weaknesses of the analytical methods used for the modeling?

(See below and Comments A4, B2, D1, G4)

			generally followed what is currently set out
			in the National Response Team's guidance
			for Monitoring during Atypical Dispersant
			Operations. In the GOM, this translates to
			the use of SSDI in deep waters below 300
			meters and below the average pycnocline.
			For the Arctic scenarios, since the ambient
			operating conditions that are present create
			limitations on the use of surface-based
			response resources much of the time, the
			use of SSDI in shallower waters was applied
			and evaluated for comparison purposes.
Resp	onse Equ	ipment Analysis Conclusions	
M1	33	One reviewer stated that a major	BSEE partially agrees. Due to the nature of
		conclusion of the study was that	how oil spills spread, are transported and
		response countermeasures employed	weather in the offshore environment, an
		against an overwhelming WCD have	important observation of the study is that
		limited success. For example, see the	most responses will have low numbers for
		DWH baseline: dispersant 8%, in-situ	the percentages of oil recovered, chemically
		burning 5%, mechanical removal 4%	dispersed, and/or burned. This is an
		(pages 237-239)	important fact of life for most oil spills
			originating in the offshore environment,
			which carries important ramifications for
			managing public expectations during a
			response. However, the study also showed
			that under favorable environmental forcing
			conditions, with the right amounts and types
			of equipment, very effective responses can
			be mounted that significantly reduces the
			amount of oiling that occurs in the
			environment. BSEE does not agree with the
			reviewer's observation that a response to a
			WCD, by default, can never be more than
			marginally effective.
M2	34, 39	One reviewer stated that a major	BSEE agrees that effective temporary source
		conclusion for the study is that source	control measures, if quickly implemented,
		control has the most significant impact in	can result in the most significant reductions
		reducing WCD exposures (page xii). This	in the amount of oil discharged into the

		recommendations for mechanical	
		recovery met the study's root objectives.	
N17	40	For NAT 25, under Specific Observations	BSEE disagrees with this comment. One of
		(for page 290, paragraph 4), one	the observations drawn from the modeling
		reviewer stated that the	of the various scenarios was that matching
		recommendation that ERSP thresholds be	the WCD volume to a commensurate
		significantly greater than the WCD is not	amount of recovery capability often is not
		supported by the modeling. The reviewer	adequate to prevent significant oiling of
		noted that ERSP ratings are already lower	sensitive environmental compartments (such
		than EDRC values. This reviewer stated	as coastal shoreline habitats). While it is
		that the modeling showed that present	difficult to state what level of resources is
		removal capability was not maximized	necessary to prevent or minimize such oiling,
		due to limitations of daylight and	it was observed in the study that, in general,
		weather (see summarization on page 290	having a greater amount of removal capacity
		in paragraph 2). This reviewer expressed	that exceeds the WCD amount generally
		concerns that requiring a significantly	resulted in better environmental outcomes.
		higher capacity for removal was not	This observation was readily apparent when
		consistent with modeling conclusions.	environmental forcing conditions were
			generally favorable for oil removal. In fact,
			the study states in the paragraph referenced
			by the reviewer "overall, the model results
			suggest that the removal potential of the
			combined response countermeasures must
			be significantly greater than the volume of
			the oil discharged in order to achieve
			significant oil removal levels in large WCD
			events."
			It was also observed, however, that in some
			of the less favorable scenario simulations,
			the modeling demonstrated that there is a
			point where increasing mechanical recovery
			resulted in levels of diminishing returns with
			regard to oil removal. This level of
			diminishing returns is likely not a single fixed
			number; rather, it is going to be lower when

#	Page	Peer Review Comment	Agency Response
			conducting recovery operations in
			unfavorable conditions, and higher when
			engaged in favorable conditions.
			The analysis also recognized that there are
			practical limits for how much equipment can
			be maintained and stockpiled in a high state
			of readiness and still be economically
			sustainable.
			In an attempt to address all these factors,
			the study recommends a scaled set of
			requirements that involves higher ratios of
			equipment for most WCD scenarios, and
			adopts gradually decreasing ratios as the
			WCD volumes get larger. These lower ratios
			are the result of setting "caps" on the
			capacity levels that are required to be
			maintained for the largest of the WCDs
			(which reflects the idea that there are limits
			to what size equipment caches can be
			economically sustained in a high readiness
			nosture) That said where existing
			equipment stockniles do allow for resources
			to be maintained and deployed in higher
			ratios this is a desirable state of readiness
			that may result in more favorable
			environmental outcomes if the right ambient
			conditions are present
			Additional Note: Due to the fact that oil
			rapidly thins on the surface and spreads out
			geographically over a very large area, there
			is an "areal coverage" aspect to oil removal
			that is often overlooked when assessing
			resources Increasing the number of
			skimming assets employed will increase the
			areal footprint that can be covered for oil
			removal, which may in fact he more
			important than necessarily increasing the
			"volume" component for oil recovery in
			many spill situations. Unfortunately trying
			to compare the areal footprint of the oil
			simulation with the areal footnrint of the
			removal resources and conduct a sensitivity
			analysis on that aspect of the response was
			here have been a second and a shifting of the
			modeling done for this study

The experimental-testing of dispersant application rates in an intentional discharge or a spill-of-opportunity are outside of BSEE's authorities and jurisdiction, and also beyond the proper scope of the study. It is not possible for BSEE to draft a preparedness regulation that would authorize a responsible party to test dispersants on an
N19 N20 N21	40 40 40	One reviewer commented that the recommendations on dispersant stockpile requirements met the study's root objectives. For NAT 37, one reviewer agreed that BSEE should promote additional research in order to establish improved guidance regarding SSDI DORs. The reviewer argued that improved guidance should include additional experimental modeling. Assuming that experimental modeling might be either cost prohibitive or impossible given the need to obtain environmental permits, the reviewer suggested that BSEE write a regulation that would allow the responsible party for the next spill to test different DORs and demonstrate a minimum DOR that satisfies their SSDI objective. The reviewer stated that	Noted. BSEE agrees. BSEE acknowledges that additional research on dispersant-to-oil application ratios for subsea discharges would be beneficial to determining what are appropriate dispersant stockpiles. However, this recommendation is outside of the scope of the study. While BSEE understands the need for more experimental data, BSEE does not agree with the recommendation as written. The experimental-testing of dispersant application rates in an intentional discharge or a spill-of-opportunity are outside of BSEE's authorities and jurisdiction, and also beyond the proper scope of the study. It is not possible for BSEE to draft a preparedness regulation that would authorize a responsible party to test dispersants on an actual spill, as the use of dispersants on any
